Abstract

Purpose: Combination of benzoyl peroxide (BPO) with topical antibiotics can lead to higher efficacy and less bacterial resistance, but it in turn increases adverse effects such as skin irritability and dryness. In this study, the efficacy of combination therapy of niosomal BPO 1% and clindamycin (CL) 1% is compared with niosomal CL in acne vulgaris.

Methods: This is a double-blind clinical trial study on 100 patients with acne vulgaris in Afzalipour hospital in Kerman. Patients were randomly divided into 2 groups (case and control). The case group received niosomal combination of BPO 1% and CL 1%. The control group received niosomal CL 1%. The efficacy of treatment protocols was evaluated in 2nd, 4th, 8th and 12th weeks of treatment by counting lesions (severity and grading acne lesions) and quality of life (QoL). Furthermore, side effect were evaluated at each treatment visits.

Results: The reduction in mean percentage of acne lesions in case group (treated with BPO 1% and CL 1%) (64.21%) was higher than control group (treated with niosomal CL 1%) (59.04%), but the statistical difference was not significant. Sum of excellent and good results were found in 80% and 76.1% of case and control groups, respectively (P = 0.377). Also adding BPO to the treatment formulation in case group did not increase adverse effects, as statistical difference between 2 groups was not significant.

Conclusion: Combination of niosomal BPO 1% and CL 1% in treatment of acne vulgaris showed higher efficacy with no increase in adverse effects in comparison with niosomal CL 1%, but the statistical difference was not significant.

Introduction

Acne is a chronic inflammatory disorder of sebaceous unit that affects most frequently adolescents and young adult. Obstruction of follicular ducts due to impacted sebaceous and keratin secretions in accompaniment with Propionibacterium acne colonization contribute to the pathogenesis of acne vulgaris. Different types of drugs such as keratolytic, antibacterial and retinoid can be used in treatment of acne. Topical antibiotics including erythromycin, clindamycin (CL) and azelaic acid have bactericidal and anti-inflammatory effects. CL is a lincosamide antibiotic that inhibits bacterial protein synthesis. Furthermore, CL reduces production of free fatty acids (by inhibition of lipase) and inhibits chemotaxis of leukocytes and pro-inflammatory cytokines. Using such drugs as monotherapy for more than 3 months or as maintenance is not recommended due to probable bacterial resistance.

Benzoyl peroxide (BPO) has lipophilic properties (leading to better penetration through stratum corneum), keratolytic and bactericidal effects. Combination of BPO with topical antibiotics can lead to higher efficacy and less bacterial resistance at the cost of more side effects such as local irritability, peeling, dryness and burning sensation that is dose dependent.

Niosomes are new drug delivery systems (NDDSs) with submicron particle size that can easily fuse in stratum corneum or pass through intra-epidermal channels and selectively affect target organ. In addition, more thermal stability and less oxidation capability of non-ionic surfactants in comparison to phospholipids (main constituents of liposomes) makes niosomes more favorable NDDS for topical delivery of active pharmaceutical ingredients. Based on our knowledge this is the first...
Evaluating efficacy of combination therapy with niosomal benzoyl peroxide and clindamycin

Advanced Pharmaceutical Bulletin, 2019, Volume 9, Issue 4

According to Global Acne Grading System (GAGS) was used. The lowest score represents the worst QoL.

**Niosome preparation technique**
Non-ionic surfactant vesicles were prepared by film hydration method. Briefly, lipid phase containing nonionic surfactant/cholesterol (7/3 molar ratio) was dissolved in 5 mL of chloroform and the organic solvent was eliminated by using rotary evaporator (Büchi Labortechnik AG, Switzerland) at 65°C. Thin lipid film was hydrated with 5 mL CL solution (1% w/v in phosphate buffered saline, pH 6.8) at 65°C for 30 minutes. Niosomal suspensions were kept in glass type I vials for further studies at refrigerator temperature. For BPO lipid vesicles, similar method was used, but BPO and lipids were dissolved in ethanol 96/chloroform (50/50 v/v) and the final concentration of BPO in niosomal formulations was 1% w/v.

**CL and BPO concentrations measurement**
Ultraviolet (UV) first derivative spectrophotometric method has been developed for determination of CL in free and niosomal formulations at 251 nm with linearity range 60-200 µg/mL in deionized water. BPO was dissolved in ethanol 96 and UV spectrophotometry was used at 244 nm for its concentration measurement.

**Encapsulation efficiency determination**
To determine the amount of the drug, 1 mL of isopropyl alcohol was added to the pellet to dissolve the walls of the niosomes and then the UV-visible spectrophotometer was used. In the case of CL, the second derivative of the UV spectrum was used.

**CL and BPO release study**
For release study of CL and BPO from niosomes, all glass Franz diffusion cell was used. The used diffusion cell had a receptor compartment volume of about 37 mL. Then, 1 mL of the product was placed on the cellophane membrane. To conduct the delivery test, the cellophane membrane was first submerged in the recipient phase for 24 hours to maintain a membrane thickness during the test. During the test, the temperature of the enclosure around the receiver phase was kept constant by a circulating water at 37 ± 1°C. In order to prevent the accumulation of active material released, in other words, for uniform distribution of the active substance in the receiver phase and uniform distribution of the temperature, a magnetic stirrer was used at medium speed (100 ± 5 rpm). Sampling from
receiver phase was performed at 0, 15, 30, 60, 90, 120, 180, 240 min at sink conditions.

**Statistical analysis**

For descriptive analysis, we used frequency, relative frequency and mean ± standard deviation. For comparison of quantitative variables between 2 groups (age, sex, number of lesions, duration of the disease, QoL and GAGS) t independent test was used. To compare treatment efficacy and adverse effects between the 2 groups, chi-square test and Fisher exact test were used. The sample size was calculated 100 with statistical power of 80%, based upon the findings of a pilot study with percentage sum of good and excellent efficacy in case and control groups (62% and 32% respectively).

**Results**

In this study, 100 patients (50 patients in each group) with mild to moderate acne vulgaris completed the study (Figure 1). Most of the patients were female (82%) and mean age of the patients (aging from 13 to 30) was 18.64 ± 3.32. Duration of acne in case and control group was 2.30 ± 0.16 and 6.62 ± 0.28 years, respectively (P = 0.339) (Table 1).

**Assessment based on counting of acne lesions**

At the beginning of the study, mean number of total acne lesions in case and control groups was 28.16 ± 2.15 and 30.56 ± 2.76, respectively (P = 0.49). At the end of the study, these were 11.42 ± 0.91 and 10.36 ± 1.03, respectively (P = 0.44) (Figures 2-4).

**Assessment based on GAGS score**

At the beginning of the study, GAGS score in case and control groups was 14 ± 0.90 and 13.94 ± 0.43 (P value = 0.95), respectively. At the end of the study, these were as 7.76 ± 0.63 and 6.64 ± 0.46, respectively (P value = 0.15) (Table 2).

**Assessment based on percentage of reduction in acne lesions**

At the end of the treatment, rates of excellent, good, fair and poor response in case group were 18%, 62%, 20% and 0%, respectively. These rates in control group were 28.3%, 47.8%, 21.7% and 2.2%, respectively (P = 0.37).

Evaluating efficacy of combination therapy with niosomal benzoyl peroxide and clindamycin

Advanced Pharmaceutical Bulletin, 2019, Volume 9, Issue 4

Assessment based on QoL
The mean score of QoL in case group before and after the treatment was 11.89 ± 1.77 and 8.60 ± 2.52, respectively (P < 0.001). The mean score of QoL in control group before and after treatment were 11.38 ± 1.63 and 10.06 ± 2.04, respectively (P < 0.001). Also, the statistical difference between 2 treatment groups at the end of the treatment was significant (P = 0.003).

Adverse effects of treatment
Table 3 shows adverse effects of treatment in 2 groups of case and control. There was no significant difference between 2 groups regarding the adverse effects including erythema, pruritus and peeling.

Topical therapy is used as first-line of treatment in mild to moderate acne lesions based on the type and severity of the lesions (inflammatory and non-inflammatory), tolerability of patients, type of skin and comorbidities. Previous studies demonstrated that 90% of patients with acne were resistant to at least 1 topical antibiotic and efficacy of the most antibiotics decreased over time due to bacterial resistance. Nowadays, combination therapy with different mechanisms of action is preferred method of choice that leads to more response rate, lower adverse effects as well as easier application of drug.18

In the present study, the efficacy of combination therapy with niosomal BPO 1% and CL 1% versus niosomal CL 1% in acne vulgaris was evaluated. The percentage of improvement of acne lesions in the group treated with niosomal BPO 1% and CL 1% (64.21%) was found higher than niosomal CL 1% (59.04%), but the statistical difference was not significant.

In one study by Gold in 2009, mean percentage of reduction of non-inflammatory, inflammatory and total acne lesions with CL1.2% and BPO2.5% gel was estimated 48.7%, 64.1% and 52%, respectively (vs. 55.74%, 77.69% and 64.21% in our study) that was lower than the present study.19

In another study by Thiboutot and colleagues in 2008, mean rate of reduction of non-inflammatory, inflammatory and total acne lesions with CL 1.2% and BPO 2.5% was 43.2%, 54.6% and 47.9% (vs. 55.74%, 77.69% and 64.21% in the present study), respectively. Also, in Thiboutot study mean rate of reduction of non-inflammatory, inflammatory and total acne lesions with conventional CL solution was 36.2%, 46.2% and 40.4% respectively (vs. 47.5%, 71.63% and 59.04% in our study) that was far lower than the present study.20 Higher response rate to lower concentration of BPO in the current study (1%) than Gold and Thiboutot et al studies (2.5%) can be explained by niosomal formulation of BPO which leads to better delivery of drug to target organ.19,20

Modern systems of drug delivery such as niosomes have higher efficacy and lower side effects. Niosomes are characterized by vesicle structures with nanometer size

</tbody>
</table>
composed of non-ionized surfactants and cholesterol. These structures have an advantage of easy transport through bilayer lipid structure of stratum corneum. Equal efficacy is achieved with lower doses of drug due to selective absorption in target organs and better penetration of niosomal structure as a result of small size and flexibility of structure.\textsuperscript{12-14} Gupta et al in 1 in vivo study demonstrated equal therapeutic index of niosomal formulation of BPO in comparison with conventional form using 4.16 time lower dosage.\textsuperscript{21}

Today, there are few studies evaluating efficacy of niosomal formulations in acne. In 1 study in Kerman in 2017 by Mohammadi and colleagues, rate of good and excellent improvements with niosomal erythromycin solution was observed in 39.9% of patients that was lower than the present study in combination of BPO 1% and CL 1% (80%). Synergistic effect of BPO and CL due to different mechanisms of action, and lack of bacterial resistance to BPO could be due to higher efficacy in our study than Mohammadi's study. Also, the rate of good and excellent improvements with niosomal erythromycin solution (39.9%) was lower than niosomal CL (76.1%).\textsuperscript{22} This can be explained by higher rate of bacterial resistance to erythromycin than CL which leads to lower relative efficacy of erythromycin in comparison to CL.\textsuperscript{23} In the present study both groups experienced mild adverse effects which was in concordance with Mohammadi's study.\textsuperscript{22} Moreover, adverse effects such as erythema, peeling and pruritus were observed with more frequency and severity at first 4 weeks which was in agreement with Mohammadi's study. During these course of treatments patients' tolerance increased, so less severity and frequency of adverse effects was observed.\textsuperscript{23}

In one study by Kawashima and colleagues in Japan, efficacy of combination therapy of CL 1.2% plus BPO 3% was compared with CL 1.2%. In this study, mean reduction in acne lesions was statistically significant in combination group than monotherapy with CL, but higher percentage of adverse effects was observed in combination group (35.1%) than monotherapy with CL (9%). In the present study, adverse effects were observed in 30% of the patients in combination group, but most of them were mild. Moderate and severe side effects were only seen in 2 (4%) of the patients of our study, but with higher rate in Kawashima et al study.\textsuperscript{10} This can be explained by lower concentration of BPO in the current study (1%) than Kawashima et al study (3%) and niosomal formulation of BPO in the present study.

In previous studies, it has been demonstrated that combination therapy BPO with CL can target different causes of pathogenicity in acne patients and lead to higher and faster response rate in treatment, but it increased adverse effects of treatment such as irritability (especially with higher concentration of BPO) which leads to poor adherence and compliance of the patients.\textsuperscript{6,9} Niosomal structures have the advantage of selective and gradual drug release in target organ (pilosebaceous unit) which leads to lower adverse effects and more efficacy of treatment as observed in our study.\textsuperscript{14,15} Furthermore, other advantages of this type of treatment are including more adherence of patients to treatment, rapid control of inflammation, lower percentage of post inflammatory pigmentation and scar formation that is especially observed in darker skin types.\textsuperscript{24}

**Conclusion**

This study shows more reduction in acne lesions in the group treated with niosomal BPO 1% and CL 1% than niosomal CL 1%, but the statistical difference between 2 groups was not significant. Adding BPO to formulation in case group didn't lead to higher adverse effects, and no statistical difference between 2 groups was observed. So increased efficacy and less adverse effects is a major advantage of niosomal and combination formulations in treatment of acne lesions, especially in adolescents who have low compliance with higher expectations.
